## PRIORITY DOCUMENT

SUBMITTED OR TRANSMITTED IN  
COMPLIANCE WITH RULE 17.1(a) OR (b)

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

## Request for grant of a patent

(See the notes on the back of this form. You can also get an explanatory leaflet from the Patent Office to help you fill in this form)

The Patent Office

 Cardiff Road  
Newport  
South Wales  
NP10 8QQ

## 1. Your reference

 tob.2918.uk.<sup>C.F.G</sup><sub>Mr. S</sub>

## 2. Patent application number

(The Patent Office will fill in this part)

0314680.0

## 3. Full name, address and postcode of the or of each applicant (underline all surnames)

 Thomas Henry Bell  
33B St Catherine's Road  
PERTH  
PH1 5SA

Patents ADP number (if you know it)

If the applicant is a corporate body, give the country/state of its incorporation

 06285282003  
United Kingdom

## 4. Title of the invention

Improved valve system

## 5. Name of your agent (if you have one)

"Address for service" in the United Kingdom to which all correspondence should be sent (including the postcode)

 Kennedys Patent Agency Limited  
Floor 5, Queens House  
29 St Vincent Place  
GLASGOW  
G1 2DT

Patents ADP number (if you know it)

08058240002

## 6. If you are declaring priority from one or more earlier patent applications, give the country and the date of filing of the or of each of these earlier applications and (if you know it) the or each application number

Country

 Priority application number  
(if you know it)

 Date of filing  
(day / month / year)

## 7. If this application is divided or otherwise derived from an earlier UK application, give the number and the filing date of the earlier application

Number of earlier application

 Date of filing  
(day / month / year)

## 8. Is a statement of inventorship and of right to grant of a patent required in support of this request? (Answer 'Yes' if:

NO

- a) any applicant named in part 3 is not an inventor, or  
b) there is an inventor who is not named as an applicant or  
c) any named applicant is a corporate body.  
See note (d))

## Warning

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

## Notes

- If you need help to fill in this form or you have any questions, please contact the Patent Office on 08459 500505.
- Write your answers in capital letters using black ink or you may type them.
- If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- If you have answered 'Yes' Patents Form 7/77 will need to be filed.
- Once you have filled in the form you must remember to sign and date it.
- For details of the fee and ways to pay please contact the Patent Office.

Patents Form 1/77

00/2657/24-Jun-03 03:25

1 Improved Valve System

2

3 The present invention relates to a new type of valve  
4 system. In particular, it relates to a valve system  
5 which can be used to control a cistern or water tank  
6 filling, or control inflation devices.

7

8 One of the most common valves in use in the home today is  
9 the ball float valve which can be found in practically  
10 every home that contains a flushed WC or a storage  
11 system. Although there are different ball float valves  
12 on the market, the majority of differences between the  
13 valves are purely aesthetic. Although the initial cost  
14 of the ball float valve makes it a practical device for  
15 controlling water levels in the cistern, there are a  
16 number of problems with the valves that up until now have  
17 not been addressed. Firstly, maintenance of the valves  
18 after a period of time can be expensive, especially if  
19 replacement is required.

20

21 Another common problem with ball float valves is their  
22 failure, resulting in the external overflowing of water,

1 which can cause structural damage if not checked in time,  
2 in addition to a waste of energy and water.

3

4 Yet another important problem with ball float valves is  
5 that the length of the arm and ball can restrict the size  
6 and shape of the vessel into which it is fitted, this is  
7 particularly noticeable in the case of flushing systems.  
8 The fittings attached to a WC, such as the handle for  
9 flushing, and a siphon also must be arranged in a set  
10 position to accommodate the valve.

11

12 As mentioned above, some manufacturers have tried to  
13 address these problems by redesigning the ball and lever  
14 position to work within the vertical plane of the valve.  
15 Another method is to use an equilibrium type valve which  
16 has a shorter ball and lever. Nevertheless, the general  
17 problems still exist in all of these amended valve types.

18

19 Ball float valves are automatic in action, with the  
20 principal design involving the use of a buoyancy float at  
21 the end of a lever, exerting its upward force on the end  
22 of a piston or similar device to close the orifice from  
23 which water is flowing. Currently on the market the only  
24 alternatives are water storage vessels that have been  
25 fitted with special control valves, such as motorised  
26 valves, or WCs fitted with flushing valves. These  
27 alternatives can be expensive and in many cases have to  
28 be supplied from a storage system that also uses a ball  
29 float valve. All ball float valves are graded in  
30 accordance with the water pressure they are required to  
31 withstand and the orifice through which the water flows.  
32 A whole array of valves are available to cope with the  
33 different water pressures, to ensure the reasonable

1 supply of water to a cistern. The main type of ball  
2 float valves available on the market currently are high  
3 pressure, low pressure, full-way and equilibrium valve.

4

5 In a high pressure valve, the orifice will be  
6 proportionally smaller than a low pressure valve with the  
7 same rate of flow. Whereas, in a full-way valve, which  
8 is installed where low pressure flow rates exist, there  
9 is a larger orifice than that of a low pressure valve.

10 Conversely, a high pressure equilibrium valve works on  
11 the principle that it transmits equal pressure to either  
12 end of its piston, such that the buoyancy of the ball  
13 does not have to withstand the pressure on the piston.  
14 Therefore, a larger orifice can be proportionally larger  
15 to that of a high pressure valve.

16

17 It can be seen that it would be beneficial to be able to  
18 provide a new type of valve system which does not suffer  
19 the same restrictions as the ball float valve system, but  
20 which can be used to control water levels in a similar  
21 manner.

22

23 It would also be useful to provide a new valve system  
24 which is able to control other fluid levels as well, such  
25 as air levels. This could be particularly useful in  
26 situations such as flood barriers, wherein when the water  
27 level rises, an increase in air pressure can be used to  
28 inflate a flood barrier.

29

30 A yet further object of the present invention is to  
31 provide a valve system which does not face all of the  
32 limitations associated with typical ball valves.

33

1 According to a first aspect of the present invention,  
2 there is provided a valve system which comprises:  
3  
4 • a first chamber; and  
5 • a compression tube which leads into the first  
6 chamber  
7  
8 wherein the compression tube contains a first fluid and a  
9 second fluid, and wherein an increase of the second fluid  
10 in the compression tube compresses the first fluid,  
11 resulting in a transposition of pressure into the first  
12 chamber.  
13  
14 Preferably the first fluid is air.  
15  
16 Preferably the second fluid is water.  
17  
18 Preferably the compression tube comprises water level  
19 adjuster holes.  
20  
21 Preferably the water level adjuster holes are provided  
22 with a removable seal.  
23  
24 Preferably the removable seal is in the form of a  
25 moveable sleeve.  
26  
27 According to a second aspect of the present invention,  
28 there is provided a valve, as described in the first  
29 aspect, that can be used to regulate water levels in a  
30 system.  
31  
32 Preferably the first chamber contains a diaphragm valve,  
33 which itself comprises a flexible material.

- 1
- 2 Preferably the diaphragm valve further comprises a
- 3 plunger section.
- 4
- 5 Preferably the first chamber is separated from a second
- 6 chamber by an inlet hole.
- 7
- 8 Preferably the plunger is aligned with the inlet hole.
- 9
- 10 Preferably when pressure applied to one side of the
- 11 diaphragm valve, it will move to block the inlet hole
- 12 leading to the second chamber.
- 13
- 14 Preferably the second chamber is separated from a third
- 15 chamber by a flexible diaphragm.
- 16
- 17 Preferably the third chamber comprises an inlet.
- 18
- 19 Preferably the third chamber comprises an outlet.
- 20
- 21 Preferably the outlet is a water outlet.
- 22
- 23 Preferably the outlet leads to a cistern.
- 24
- 25 Preferably the flexible diaphragm contains a metering
- 26 hole through which fluid can flow.
- 27
- 28 Preferably the flexible diaphragm comprises a blocking
- 29 means.
- 30
- 31 Preferably the blocking means is a washer.
- 32

1 Most preferably when there is an increase in pressure in  
2 the second chamber, the diaphragm moves such that the  
3 blocking means blocks the inlet in the third chamber.

4

5 Preferably the valve system is provided with an automatic  
6 cut-out, which itself comprises water absorbent material  
7 housed at a position within the diaphragm valve.

8

9 Preferably, in the presence of water, the water absorbent  
10 material will increase in volume, pushing the diaphragm  
11 valve to block the inlet hole.

12

13 Optionally the valve system may comprise an adjuster  
14 which is able to alter the pressure required to close the  
15 valve, wherein the adjuster comprises a compression means  
16 which is able to selectively compress the diaphragm  
17 valve, thus altering the resistance of the diaphragm  
18 valve.

19

20 Preferably the compression means comprises a screw and a  
21 spring, wherein the screw can be turned to compress the  
22 spring, which then causes resistance on the diaphragm,  
23 forcing it further away from the face of the inlet hole.

24

25 According to a third aspect of the present invention,  
26 there is provided a valve system (as described in the  
27 first aspect) that can be used in a flood defence system.

28

29 Preferably the first chamber contains an inflatable  
30 element.

31

1 Optionally, the inflatable element may be provided in a  
2 different chamber which is attached in some manner to the  
3 first chamber.

4

5 Most preferably when the pressure in the compression tube  
6 increases, the inflatable element inflates.

7

8 Most preferably the pressure in the compression tube will  
9 increase when water levels rise in the compression tube.

10

11 Preferably the compression tube is placed within a body  
12 of water and the inflatable element is positioned above  
13 or on top of the body of water.

14

15 In order to provide a better understanding of the present  
16 invention, an embodiment of the invention will now be  
17 described by way of example only and with reference to  
18 the following drawings, in which:

19

20 Figure 1 shows a Portsmouth equilibrium float valve which  
21 is part of the prior art;

22

23 Figure 2 shows a diaphragm equilibrium float valve which  
24 is part of the prior art;

25

26 Figure 3 is a diagram of the new valve system according  
27 to the present invention for use in regulating water  
28 levels, i.e., in a standard flushed WC;

29

30 Figure 4 shows a pressure spring adjuster which may be  
31 part of the new valve system according to the present  
32 invention;

33

1 Figure 5 shows a compressor spring adjuster which may be  
2 part of a new valve system according to the present  
3 invention; and

4

5 Figure 6 is a diagram of a new valve system which can be  
6 used as an automatic flood barrier according to the  
7 present invention.

8

9 ***Working Principles***

10 In order to fully understand the working principles  
11 behind the new valve system, it is important to  
12 understand force and water pressure.

13

14 Water pressure acting on the base of a tank is  
15 proportional to head and volume of liquid does not affect  
16 pressure. For example, the pressure at the base of the  
17 tank holding  $1\text{m}^3$  is the same as a tank holding  $10\text{m}^3$  with  
18 the same head of water. However, the force acting on the  
19 base of a large tank is greater. Also, it should be  
20 noted that if the base is less than  $1\text{m}^2$ , then the force  
21 will be less.

22

23 In the new valve system, one aspect of the invention is  
24 concerned with the closing off of incoming water to any  
25 cistern or tank without the use of a ball float valve and  
26 lever. The design utilises the fact that an alternative  
27 pressure can be exerted to close the orifice from which  
28 water is flowing and in fact, if required, a much greater  
29 pressure can be achieved. By experimentation, it was  
30 found that by placing a manometer tube into a tank, the  
31 head of water at the base of a tank will register a head  
32 of water on the manometer, even if the manometer tube is  
33 held above the tank. This effect occurs because the

1 force of the water at the base of the tube transposes the  
2 water pressure via the air in between the two water  
3 columns. However, it should be noted that to register  
4 nearly the same bottom tank pressure on the manometer,  
5 the volume of air between the tube must be of such a  
6 capacity that this transposition takes place with a  
7 minimal loss of registered pressure head. Therefore, too  
8 great or too little a volume of air in-between the tubes  
9 would result in the prevention of any significant  
10 movement of water in the manometer. As it is known that  
11 a fixed mass of air or any gas at a constant temperature  
12 is always inversely proportional to the pressure  
13 (according to Boyle's Law), the volume of air in between  
14 the water and the tank and the manometer can be  
15 calculated to maximise the transposition. For example,  
16 if the volume of air in a tube is halved, the pressure is  
17 doubled, and vice versa.

18

19 An example of the principles in action is shown below.

20

21 Where  $P$  = absolute pressure = 101.33kpa,  $V$  = volume,  $C$  =  
22 constant and  $P_1V_1 = P_2V_2$  (the application of this  
23 equation enables a difference in volume to be  
24 determined).

25

26 In order to find the pressures of air in a tube and  
27 confirm the pressure head, the following calculation can  
28 be carried out. The initial volume of the tube is  $\pi r^2 h =$   
29  $3.142 \times .006 \times .006 \times .480\text{m/m} = .0000542\text{m}^3$ . When water is  
30 added to create a pressure head of 300m/m, the upthrust  
31 due to the pressure reduces the height of air within the  
32 tube by 15m/m. This volume can be calculated as follows:

33

10

1  $3.142 \times .006 \times .006 \times .480 - 15\text{m/m} = .0000525\text{m}^3$

2

3  $P1 = 101.33$

4  $V1 = .0000542$

5  $V2 = .0000525$

6  $P2 = ?$

7

8 Where  $P1V1 = P2V2$ , then  $P2 = \frac{P1V1}{V2}$

9

10

11 Which  $= \frac{101.33 \times .0000542}{.0000525}$

12

13

14 Which  $= 104.66 - \text{gauge } 101.33 = 3.82\text{KN pressure in tube}$

15  $9.81$

16

17 Which  $= .334\text{m/m approximate pressure head}$

18

19 By experimentation, it was found that only 5% of pressure

20 head was lost when 300m/m head of water was applied.

21 This is due to the upthrust pressure of the water in the

22 inner tube, compressing the air until the pressure

23 equalises with the applied water pressure. When the

24 pressure head is reduced to half, the upthrust is

25 proportionally reduced.

26

27 When the volume of air within the tube is increased to

28 960m/m, the percentage of upthrust is increased, reducing

29 the pressure head.

30

31 Moreover, sealed tubes of different diameters but similar

32 lengths inserted into the water vessels for the same

11

1 pressure head will produce the same upthrust (as  
2 explained previously).

3

4 However, although a force of water can be transposed from  
5 the base of a tank to the upward area to nearly equalise  
6 against the similar force, in practice the pressure head  
7 within a cistern acting on the base would generate an  
8 insufficient force to act on a piston or similar device  
9 to close an orifice from which water is flowing.

10 However, by acting the force on a larger area, this would  
11 produce an adequate force to act on the piston or similar  
12 device to close the orifice. This is because the greater  
13 the area, equals the greater the force.

14

15 The fact that water or air pressure equalises in all  
16 directions, means that the transposition of water  
17 pressure by air from a much small area to a larger area  
18 will greatly increase its force. However, it should be  
19 noted that the air volume must be of certain cubic  
20 capacity to maximise the pressure.

21

22 The new valve system operates as there is a correlation  
23 between the size of the diaphragm and the pressure head  
24 available, i.e., the greater pressure head, the smaller  
25 the diaphragm, the smaller the pressure head the greater  
26 the diaphragm. In the present invention, due to variable  
27 water pressures and different markets, the cistern will  
28 be arranged for an option in size for the domestic  
29 market, but can be proportionally altered to be adapted  
30 for industrial uses, etc.

31

32 *Example of the New Valve System*

12

1 Figure 3 shows a figure of the new valve system for use  
2 relating to closing off automatically any incoming water  
3 to a cistern or tank. The water enters the new valve  
4 system 1 through the inlet tube 14a. It is unimpeded in  
5 flow when the valve system 1 is open. The water flows  
6 through the inlet tube 14a into the third chamber 13 and  
7 fills the cistern through the outlet tube 15. At the  
8 same time, water flows into the second chamber 11 through  
9 the metering hole 16 incorporated in the flexible  
10 diaphragm 14b. The water in the second chamber 11 seeps  
11 out through the inlet hole 12 into the first chamber 2,  
12 which prevents any build up of pressure in the second  
13 chamber 11. This results in the pressure on either side  
14 of the flexible diaphragm 14b being equalised, resulting  
15 in no movement of the flexible diaphragm 14b. In this  
16 state, the new valve system 1 is fully open.

17

18 However, as the cistern fills with water, it covers the  
19 compression tube 3 and any adjuster holes 6 that have not  
20 been covered by a removable seal 7. A pressure head of  
21 water starts to build up in the compression tube 3,  
22 compressing the air within the compression tube 3. When  
23 the water level reaches a predetermined height in the  
24 cistern to generate sufficient pressure, it acts on the  
25 diaphragm valve 8. In the preferred embodiment there is  
26 a surrounding cage around the diaphragm valve 8 which  
27 prevents any back pressure occurring, such that the valve  
28 8 extends forward, such that its plunger 10 is compressed  
29 against inlet hole 12, closing the water seepage off.  
30 When this occurs, pressure within the second chamber 11  
31 builds up until it equalises with the incoming water  
32 pressure which causes the inner flexible diaphragm 14b to

1 move forward, closing off the water from the inlet tube  
2 14a. In this state the valve is fully closed.  
3  
4 When the water level in the cistern falls, the pressure  
5 in the compression tube is reduced, which automatically  
6 results in the diaphragm valve 8 moving back, opening the  
7 inlet hole 12, such that water seepage again occurs from  
8 the second chamber 11 into the first chamber 2, and the  
9 flexible diaphragm 14b drops back into position, such  
10 that the inlet tube 14a is no longer blocked by the  
11 blocking means 17.

12

### 13 *Slide Sleeve Water Level Adjuster*

14 In order to adjust the pressure required to close off the  
15 valve system 1, the compression tube 3 may have a series  
16 of level adjuster holes 6 drilled into it at different  
17 levels. The level adjuster holes 6 are coverable with an  
18 outer removable seal 7. When this removable seal 7 is  
19 move up, it exposes a level adjuster hole 6 and breaks  
20 the pressure head allowing more water into the cistern  
21 before the diaphragm valve 8 activates. When the  
22 removable seal 7 is pushed down, it allows less water  
23 into the cistern before the diaphragm valve 8 activates.

24

### 25 *Compression Spring Adjusters*

26 Figure 4 shows an alternative adjuster that can be fitted  
27 to change the amount of water required to activate the  
28 diaphragm valve to close off the new valve system 1.  
29 These type of compression spring adjusters can be mounted  
30 at any position but usually either on top of the body of  
31 the new valve cistern 1, or in a central position, as  
32 illustrated in Figure 4. To adjust the water level, the  
33 thumb or adjuster screw 19 is turned to compress the

1 spring 18 which causes a resistance on the diaphragm  
2 valve 8, forcing it further away from the face of the  
3 inlet hole 12. Therefore, more water has to enter the  
4 cistern to build up a greater pressure head to push the  
5 diaphragm valve 8 forward further to close the inlet hole  
6, 12.

7

### 8 **Automatic Cut-out**

9 An automatic cut-out can be included in the new valve  
10 system 1 to ensure that if the new valve system 1 fails,  
11 and the water levels in the cistern rise to an  
12 undesirable level, an automatic cut-out will occur.  
13 Figure 5 shows a diagram of the automatic cut-out system.  
14 The automatic cut-out consists of a number of water  
15 absorbent washers 20 housed in a cup-type chamber 21  
16 positioned in the diaphragm valve 8. If, during  
17 operation, the new valve system 1 fails and does not  
18 cause the diaphragm valve 8 to push forward to close the  
19 inlet hole 12, water would automatically enter the first  
20 chamber 2 behind the diaphragm valve 8. If this occurs,  
21 the water absorbent washers 20 housed within the chamber  
22 will automatically increase in volume due to water  
23 absorption. This increase in volume will force a cut-out  
24 plunger 22 attached to the water absorbent washers 20 to  
25 move forward, pushing the normal plunger 10, such that it  
26 closes the inlet hole 12. In this manner, any  
27 overflowing or wastage of water will be prevented, even  
28 if the new valve system 1 fails for any reason.

29

### 30 **Alternative Embodiments**

31 Although the new valve system can be ideally used to  
32 regulate water flow in a cistern, as described in the  
33 preferred embodiment, it also has a number of other uses.

15

1 Figure 6 shows a diagram of another possible use for the  
2 new valve system 1, as an automatic flood barrier. It  
3 can be seen that as in the previous embodiment there is a  
4 compression tube 3 and level adjuster holes 6 and a  
5 removable seal 7 can be included, if required. The  
6 compression tube 3 leads to your first chamber 2, which  
7 itself incorporates a flexible material 9. However,  
8 instead of the flexible material 9 being in the form of a  
9 diaphragm valve 8, as in the previous embodiments, the  
10 flexible material will inflate in response to an increase  
11 in pressure in the compression tube 3. It can be seen  
12 that the flexible material does not necessarily have to  
13 be in a first chamber, but may be in a second, third or  
14 fourth chamber, etc., which is joined to the first  
15 chamber in some manner. If this system is used in a  
16 river, the compression tube 3 will be used on the river  
17 bank with the first chamber 2 incorporating the flexible  
18 material 9 being present on the riverbank. As river  
19 levels rise, water will enter the compression tube 3 at  
20 higher and higher levels, causing the flexible material 9  
21 to inflate in response to the pressure increase within  
22 the compression tube.

23  
24 Another embodiment would use the valve as a containment  
25 barrier for oil spills and such the like. In this  
26 embodiment again the compression tube 3 leads to a first  
27 chamber 2, which itself incorporates a flexible material  
28 9. When dropped into a body of liquid such as the sea  
29 around the periphery of an oil or chemical spill the  
30 flexible material will inflate to form a containment  
31 barrier. The compression tube and any internal valve  
32 units (if required) will be prepared such that as soon as

16

1 the compression tube 3 is place in position the pressure  
2 would be sufficient to immediately inflate the barrier.

3

4 It can be seen that the valve system has a number of  
5 advantages over prior systems, in that it can be  
6 manufactured in a compact manner, it is easy to install  
7 and use, and maintenance costs should be relatively low.

8

9 The embodiments disclosed above are merely exemplary of  
10 the present invention, which may be embodied in different  
11 forms. Therefore, the details disclosed herein are not  
12 to be interpreted as limiting, but merely as a basis for  
13 the claims and for teaching one skilled in the art as to  
14 the various uses of the present invention in any  
15 appropriate manner.
